

Deployment Guide

This guide describes shipping services to the cluster.

Build images with docker and tag them with the commit sha.

Push images to the private registry before deploying.

Never run containers as root; drop privileges in the image.

Rollouts

Package applications as Helm charts with values per environment.

Perform a canary rollout by shifting five percent of traffic.

Roll back immediately when error rates cross the threshold.

Monitor rollouts with `kubectl rollout status`.

Pipelines

A CI pipeline runs tests, builds images, and deploys to staging.

Use the pipeline to gate production releases on green tests.

Secrets live in the vault, never in the repository.

On failure the pipeline reports the failing stage and logs.
